

# MRI Approaches for Investigating Brain Structure and Function

Jason S. Nomi, Ph.D. ([jxn131@miami.edu](mailto:jxn131@miami.edu))

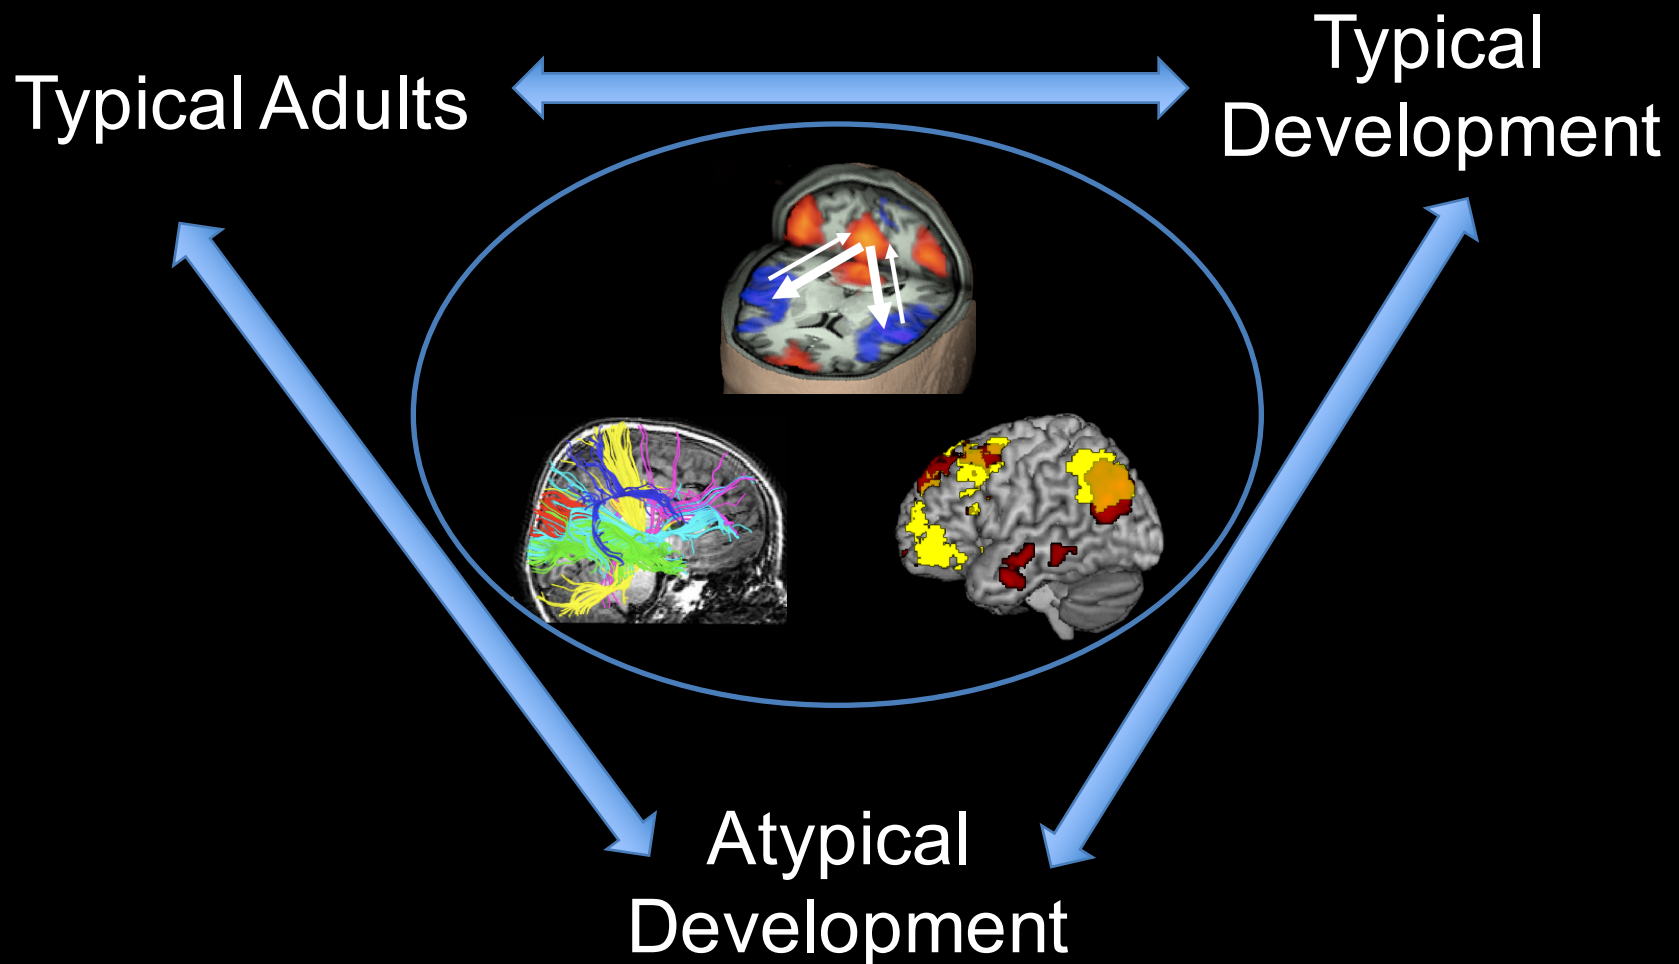

# Cognitive Neuroscience

“the scientific study of biological substrates underlying cognition, with a specific focus on the neural substrates of mental processes...addresses the questions of how psychological functions are produced by the brain”

# Research Approach in Our Lab

# Critical Research Questions

**Brain Network  
Development**

**Cognitive  
Maturation**

# Timeline for development of methods in cognitive neuroscience

# Methods in Cognitive Neuroscience

<b>Method</b>	<b>Method type</b>	<b>Invasiveness</b>	<b>Brain property used</b>
EEG/ERP	Recording	Non-invasive	Electrical
Single-cell (and multi-unit) recordings	Recording	Invasive	Electrical
TMS	Stimulation	Non-invasive	Electromagnetic
MEG	Recording	Non-invasive	Magnetic
PET	Recording	Invasive	Haemodynamic
fMRI	Recording	Non-invasive	Haemodynamic

EEG = electroencephalogram, ERP = event-related potential, TMS = transcranial magnetic stimulation, MEG = magnetoencephalography, PET = positron emission tomography, fMRI = functional magnetic resonance imaging

# Imaging methods can vary in several ways

- The **temporal resolution** refers to the accuracy with which one can measure *when* an event is occurring. The effects of brain damage are permanent and so this has no temporal resolution as such. Methods such as EEG, MEG, TMS and single-cell recording have millisecond resolution. PET and fMRI have temporal resolutions of minutes and seconds, respectively, that reflect the slower haemodynamic response.
- The **spatial resolution** refers to the accuracy with which one can measure *where* an event is occurring. Lesion and functional imaging methods have comparable resolution at the millimetre level, whereas single-cell recordings have spatial resolution at the level of the neuron.
- The *invasiveness* of a method refers to whether or not the equipment is located internally or externally. PET is invasive because it requires an injection of a radio-labelled isotope. Single-cell recordings are performed on the brain itself and are normally only carried out in non-human animals.

# Methods Compared

# Electrical Recordings

- Direct measure of neural activity using implanted electrodes
- Sometimes called intracranial EEG

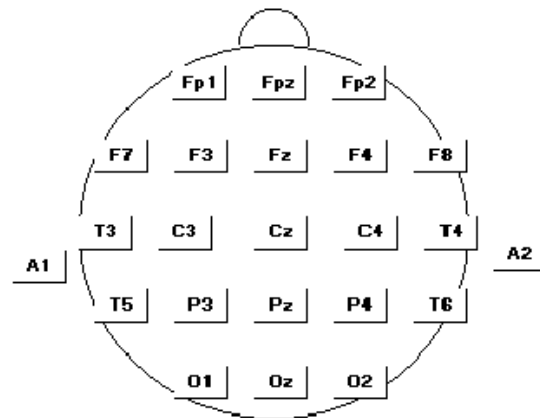

# Advantages and disadvantages to electrical recordings

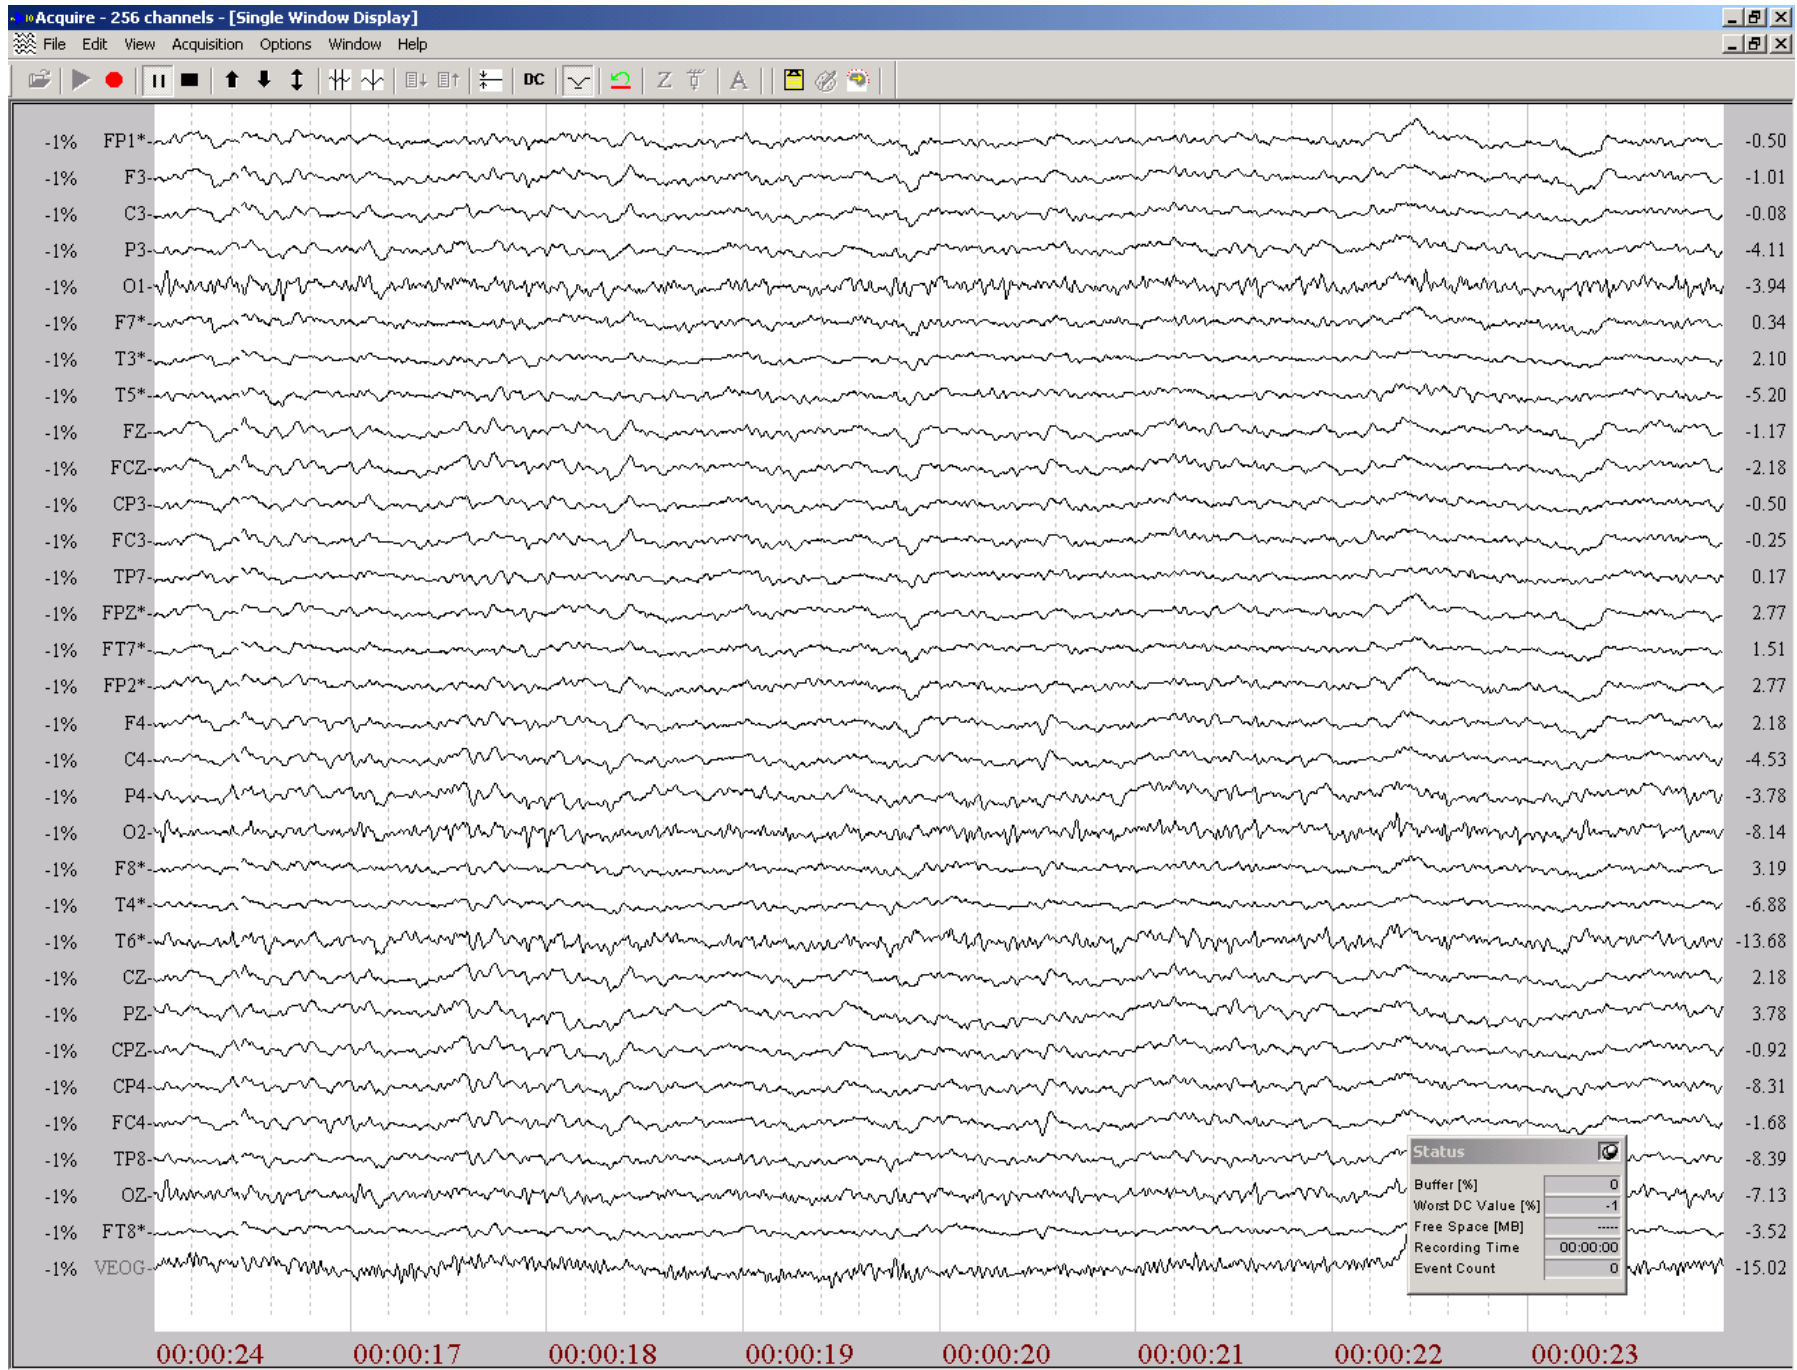

- Strengths: very high spatial and temporal resolution
- Weaknesses: invasive, can rarely be carried out in humans, most useful for researchers who use animal models

# Electroencephalogram (EEG)

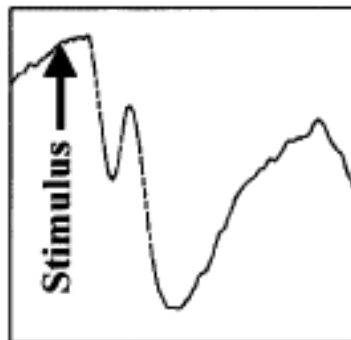

- Recording of electrical activity along the scalp produced by firing of neurons in the brain
- EEG activity reflects the sum of activity across millions of neurons with similar orientations

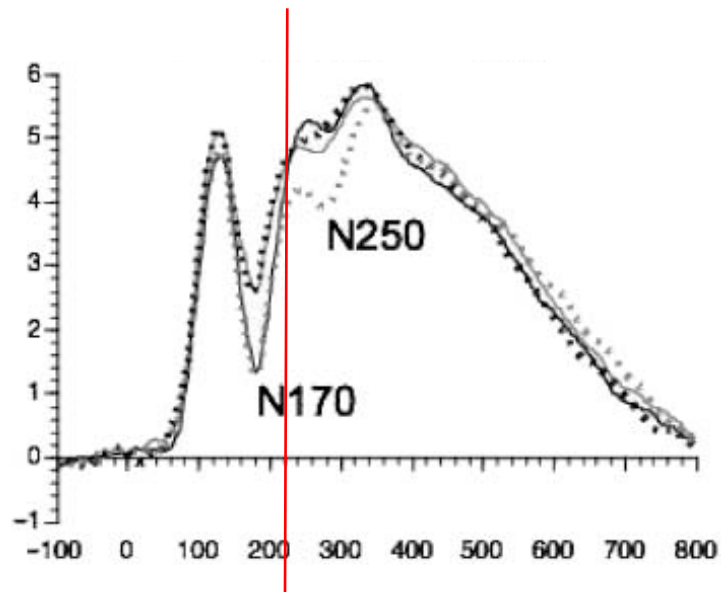

# Event-related potentials (ERPs)

- Measure continuous EEG while subject performs a psychological task
- Average the EEG waveform surrounding an event of interest (a stimulus or response)

# Advantages and Disadvantages of ERPs

- Strengths: Very fine temporal resolution (milliseconds), can tolerate subject movement, machine is silent, equipment is relatively cheap compared to fMRI
- Weakness: Hard to localize source of electrical activity (low spatial resolution), messy

# Magnetoencephalography (MEG)

- Mapping brain activity by recording magnetic fields produced by electrical currents in the brain

# Advantages and disadvantages of MEG

- Strengths: non-invasive, very high temporal resolution (can detect events with precision of 10 milliseconds). High spatial resolution.
- Weaknesses: the magnetic field created by neural activity is very weak and difficult to detect, it is difficult to localize the source of the signal (but better than EEG). Cost.

# Positron Emission Tomography (PET)

- Inject radioactively-labeled compound into the blood stream
- Detectors detect radioactive emissions and build an image of where in the brain the radioactive substance is concentrated

---

# PET Images

# Advantages and Disadvantages to PET

- Strengths: useful in diagnosis of brain disease and assessing biochemical function in brain
- Weaknesses: invasive, radioactive tracers must be injected into the patients' bloodstream, high cost of producing radiotracers

# Magnetic Resonance Imaging (MRI)

# Magnetic Resonance Imaging

- Relatively new method, first used in humans in the 1970' s

# Advantages and Disadvantages to MRI

- Strengths: Excellent spatial resolution. Greater contrast between tissue types than CAT (high spatial resolution), does not expose subjects to radiation.
- Weaknesses: Poor temporal resolution. Expensive (compared to ERP), subjects have to remain very still for several minutes, the machine is very loud

# Acquiring the MRI signal

# Structural vs. Functional MRI

- Structural Measures
  - Gray and white matter volume/density
  - Cortical thickness
  - Gyrification
- Functional Measures
  - BOLD signal (activation)
- Diffusion Measures
  - Water Movement
  - Axonal pathways

# Functional MRI (fMRI)

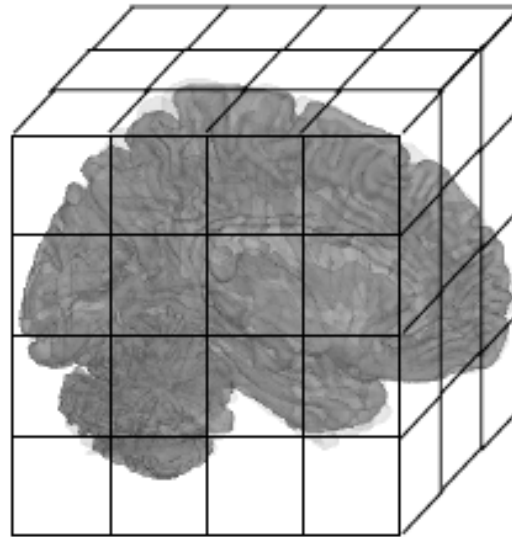

- Uses MRI technique to map functional changes in brain activity
- fMRI measures changes in cerebral blood flow
- Blood flow (BOLD signal) is related to neural activity

**Figure 1.** During periods of neuronal activity, local blood flow and volume increase with little or no change in oxygen consumption. As a consequence, the oxygen content of the venous blood is elevated, resulting in an increase in the MR signal.

# Functional MRI

- Each image consists of  $\sim 100,000$  voxels (3d pixels/cubic volumes) that span the entire space of the brain

From Martin Lindquist: Coursera

# Functional MRI

- Each voxel corresponds to a spatial location and has a number associated with it that represents its intensity

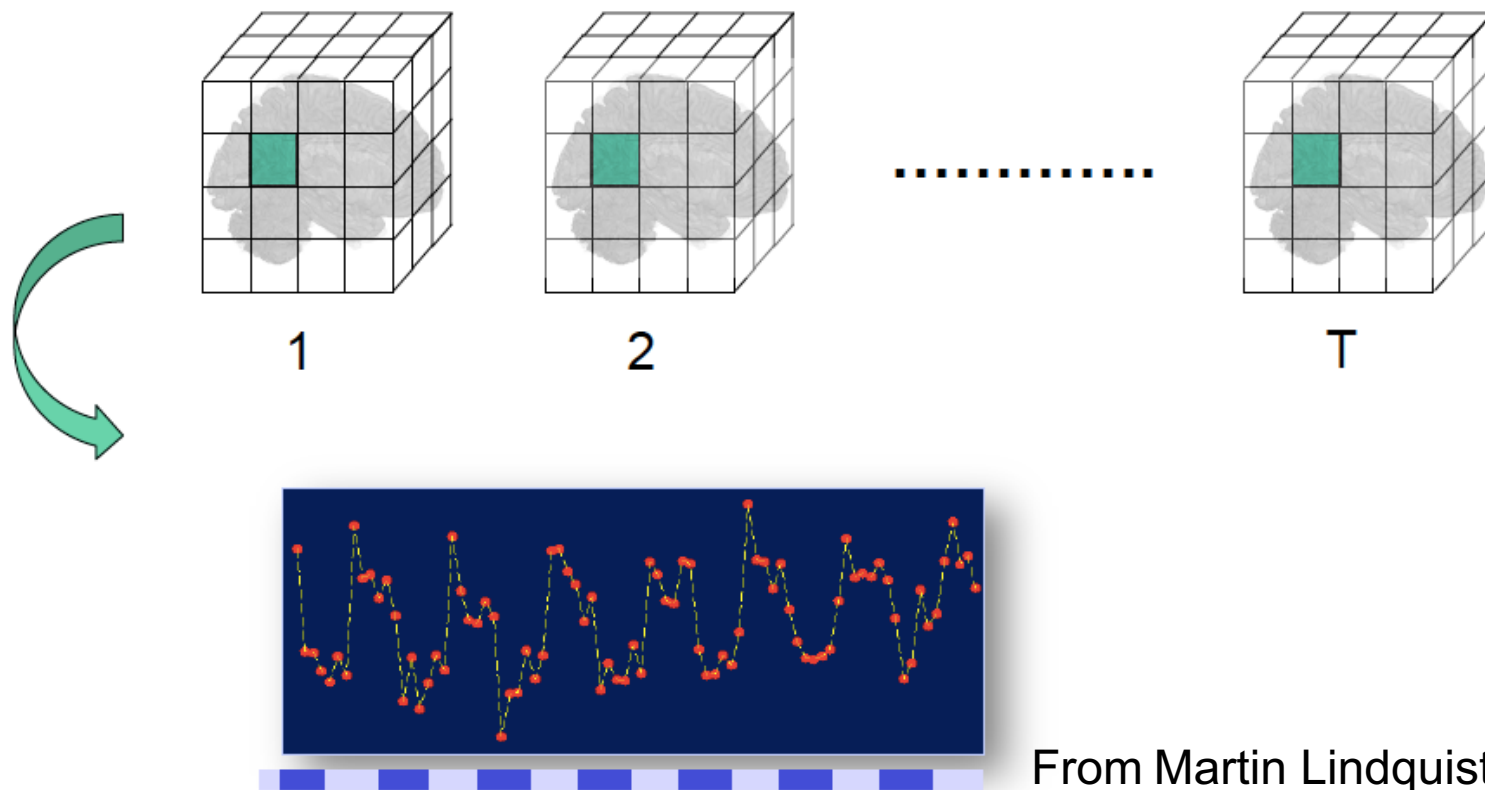

# Functional MRI

- During the course of an experiment, several hundred images may be acquired (if  $TR = 2$ , one acquisition every 2s)

# Functional MRI

- Tracking the intensity over time at each voxel gives us a “time series”

From Martin Lindquist: Coursera

# Functional MRI

- Most commonly used approach in fMRI is Blood Oxygenation Level Depended (**BOLD**) contrast
- BOLD fMRI measures the **ratio** of oxygenated to deoxygenated hemoglobin in the blood
- So, fMRI measures oxygen consumption of active neurons (**NOT neural activity directly**)

# fMRI Data

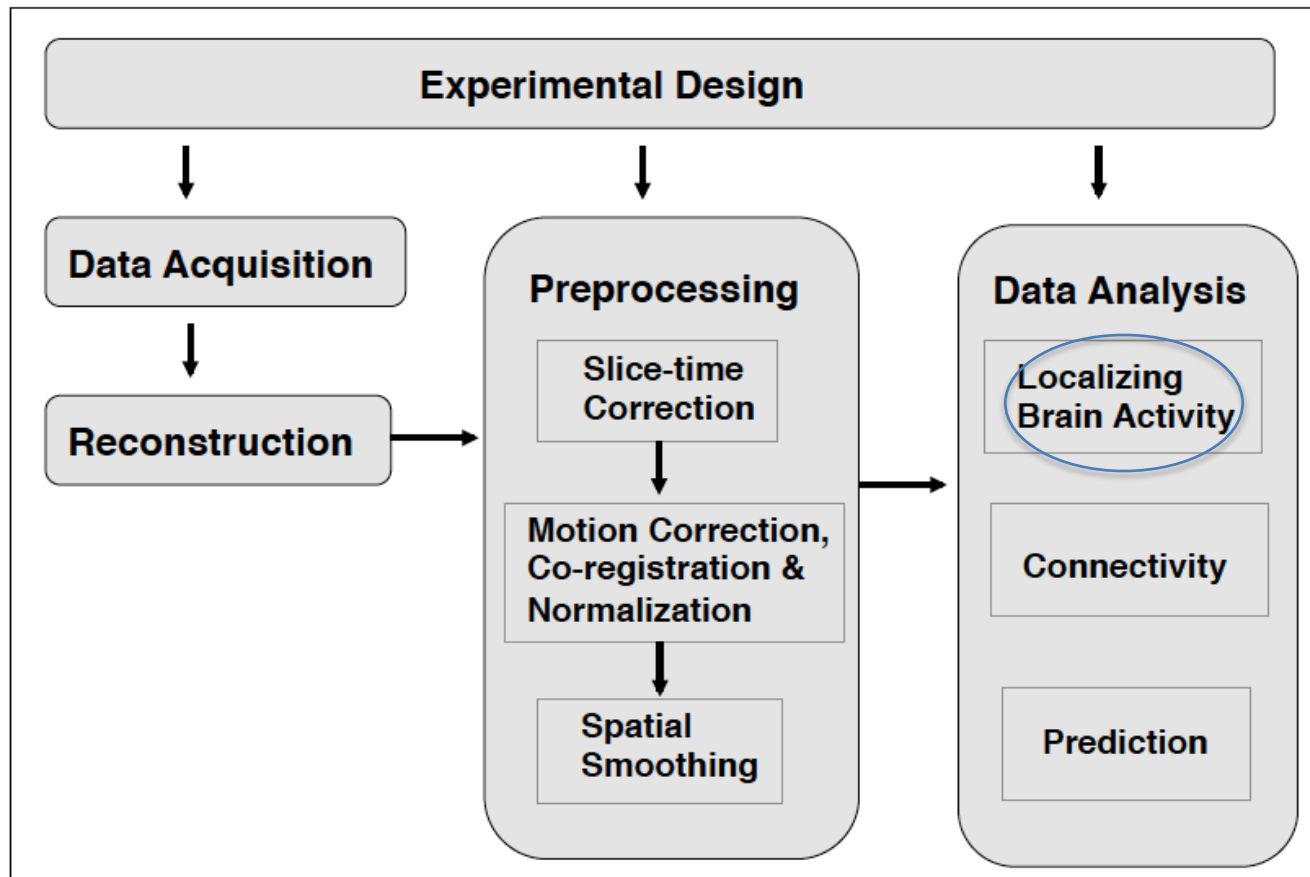

- fMRI data analysis is a massive data problem
  - Each brain volume consists of ~100,000 voxel measurements
  - Each experiment consists of hundreds of brain volumes
  - Each experiment may be repeated for multiple subjects to facilitate population inference
- This makes for a lot of data!

# Statistical analysis of fMRI data

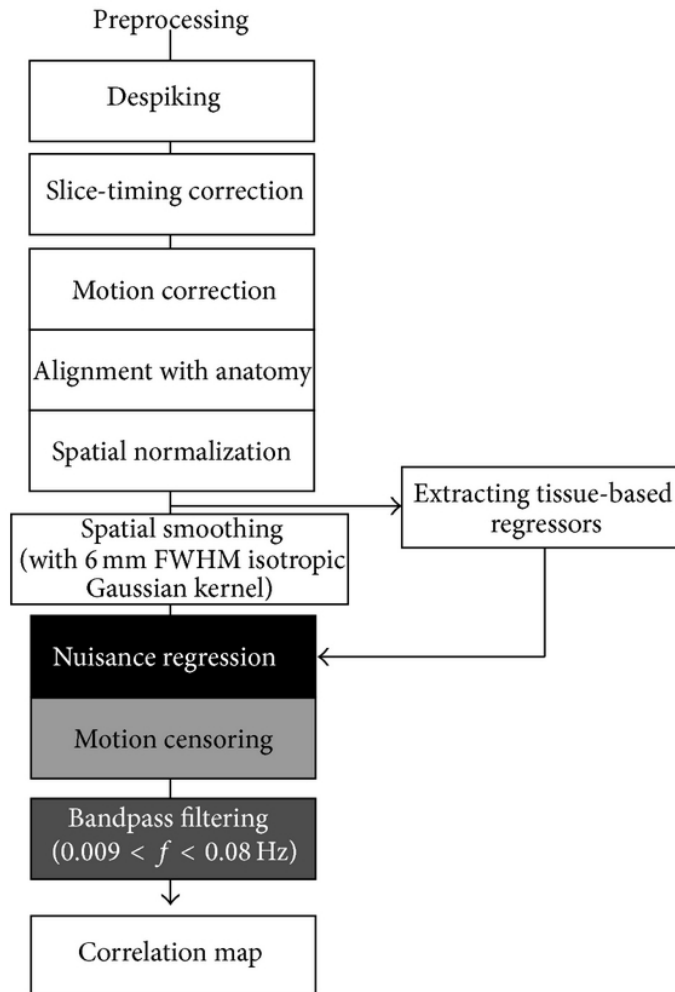

- Massive data problem
- Signal of interest is relatively weak
- The data exhibits a complicated temporal and spatial noise structure

# Data processing pipeline

From Martin Lindquist: Coursera

# Preprocessing Pipeline Example

Order and specific steps can change depending on your analysis

# fMRI Experiments

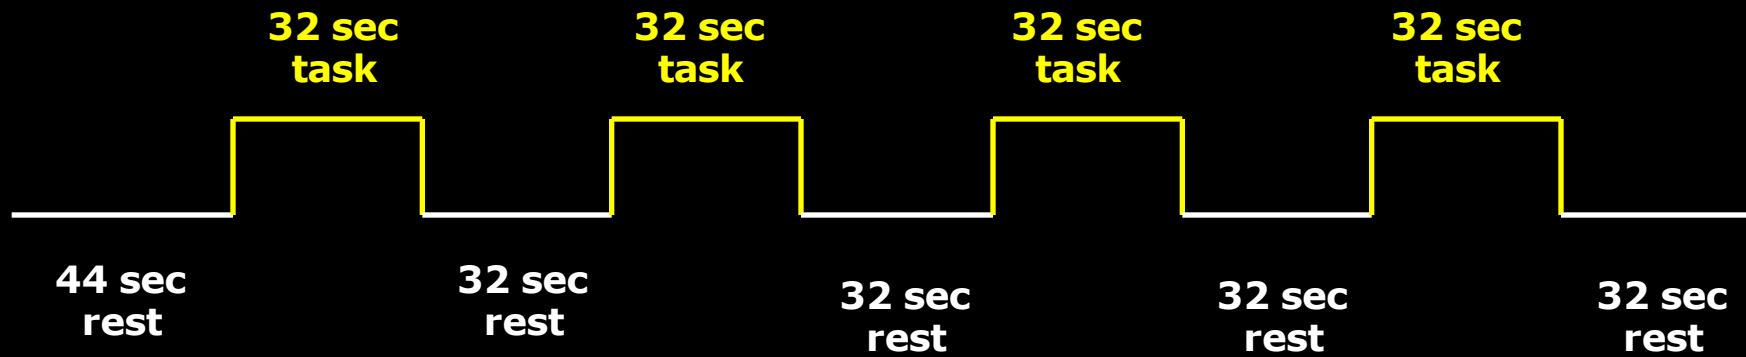

- Participant performs a psychological task in the scanner
- Must be a baseline or control condition for comparison

# Task based fMRI

- Correlation between BOLD signal and event of interest....

# Network Neuroscience (Connectivity)

The quick fox jumped  
over the lazy dogs

# Rest vs. Task

- What is your brain doing?

Vs.

- Early assumption in fMRI
  - The brain needed to be doing a task to identify coherent patterns of activity

# “Resting” State Networks

- Organized intrinsic structure
  - Newborns
  - Sleep
  - Monkeys
  - Rats
- Backbone of thought and cognition?
- “Resting state”
  - Misnomer
  - Brain is always active with coherent structure

# Independent Component Analysis (ICA)

- “Cocktail Party” problem
  - Mix of voices
    - Different frequencies, different patterns of soundwaves
- Brain
  - Different patterns of blood flow
  - Identify voxels of the brain where blood flow is similar to each other, but different from other voxels

# Flexible Cognition in Autism Spectrum Disorder (ASD)

- Flexible Cognition

- Quickly adapt and respond to your environment
- Facilitate learning and personal growth

- ASD

- Affects nearly 1:68 children (CDC, 2016)
- Family life, School life, Work life

Restricted and Repetitive Behaviors in ASD

Behavioral Inflexibility ↔ Cognitive/Neural Inflexibility (Geurts et al., 2009)

# Restricted and Repetitive Network Switching

- 40 (Typical)
- 34 (ASD)
  - 18-39 years old
