### Outline

Representations in Computer Vision

2 Visualizing & Understanding of CNNs

③ Filtering

Filtering

Detectors

References

## From 3D world to 2D images

- So far we have focused on mapping 3D objects onto 2D images and on leveraging such mapping for scene reconstruction
- Next step: how to represent images and infer visual content?

## Today's lecture

### • Aim:

- Learn fundamental tools in image processing for filtering and detecting similarities
- Learn how to detect and describe key features in images

### • Readings:

• Siegwart, Nourbakhsh, Scaramuzza. Introduction to Autonomous Mobile Robots. Sections 4.3 – 4.5.4.

Filtering •000000000 Detectors

References

# Image filtering

- Filtering: process of accepting / rejecting certain frequency components
- Starting point is to view images as functions *I* : [*a*, *b*] × [*c*, *d*] → [0, *L*], where *I*(*x*, *y*) represents intensity at position (*x*, *y*)
- A color image would give rise to a vector function with 3 components

Filtering

Detectors

# Spatial filters

### A spatial filter consists of

- A neighborhood  $S_{xy}$  of pixels around the point (x, y) under examination
- A predefined operation F that is performed on the image pixels within  $S_{xy}$

**Detectors** 

## Linear spatial filters

- Filters can be linear or non-linear
- We will focus on linear spatial filters

$$\underbrace{I'(x,y)}_{Filtered image} = F \circ I = \sum_{i=-n}^{n} \sum_{j=-m}^{m} \underbrace{F(i,j)}_{Filter mask} \underbrace{I(x+i,y+j)}_{Original image}$$

- Filter F (of size (2N + 1)x(2M + 1)) is usually called a mask, kernel, or window
- Dealing with boundaries: e.g., pad, crop, extend, or wrap

Filtering

**Detectors** 

References

## Filter example #1: moving average

- The moving average filter returns the average of the pixels in the mask
- Achieves a smoothing effect (removes sharp features)
- E.g., for a *normalized* 3x3 mask

Generated with a 5x5 mask

Filtering

Detectors

References

## Filter example #2: Gaussian smoothing

Gaussian function

$$\mathcal{G}_{\sigma}(x,y)=rac{1}{2\pi\sigma^2}\exp(-rac{x^2+y^2}{2\sigma^2})$$

- To obtain the mask, sample the function about its center
- $\bullet\,$  E.g., for a normalized 3x3 mask with  $\sigma=0.85$

$$G = \frac{1}{16} \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$$

<ロ><回><回><回><回><回><回><回><回><回><回<</p>

Vis. & Underst. of CNNs

Filtering

Detectors

## Convolution

• Still a linear filter, defined as

$$I'(x,y) = F * I = \sum_{i=-n}^{n} \sum_{j=-m}^{m} F(i,j)I(x-i,y-j)$$

- Same as correlation, but with negative signs for the filter indices
- Correlation and convolution are identical when the filter is symmetric
- Convolution enjoys the associativity property

$$F*(G*I)=(F*G)*I$$

• Example: to smooth an image & take its derivative = create a combined filter by convolving a derivative filter with a Gaussian filter & convolving the resulting combined filter directly with the image to achieve smoothing and differentiation in one step

Filtering

**Detectors** 

## Separability of masks

• A mask is separable if it can be broken down into the convolution of two kernels

$$F = F_1 * F_2$$

- If a mask is separable into "smaller" masks, then it is often cheaper to apply  $F_1$  followed by  $F_2$ , rather than F directly
- Special case: mask representable as outer product of two vectors (equivalent to two-dimensional convolution of those two vectors)
- If mask is  $M \times M$ , and image has size  $w \times h$ , then complexity is
  - $O(M^2wh)$  with no separability
  - O(2Mwh) with separability into outer product of two vectors

Filtering

Detectors

References

## Example of separable masks

Moving average

$$F = \frac{1}{9} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \cdot \frac{1}{3} \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}$$

• Gaussian smoothing

$$egin{aligned} G_\sigma(x,y) &= rac{1}{2\pi\sigma^2}\exp(-rac{x^2+y^2}{2\sigma^2}) \ &= rac{1}{2\pi\sigma^2}\exp(-rac{x^2}{2\sigma^2})rac{1}{2\pi\sigma^2}\exp(-rac{y^2}{2\sigma^2}) \ &= g_\sigma(x)\cdot g_\sigma(y) \end{aligned}$$

Vis. & Underst. of CNNs

Filtering

Detectors

References

## Differentiation

Used to detect gradients and edges in the x and y-directions of an image

• Derivative of discrete function (centered difference)

$$\frac{\delta I}{\delta x} = I(x+1, y) - I(x-1, y) \qquad \begin{bmatrix} 1 \ 0 - 1 \end{bmatrix}$$
$$\frac{\delta I}{\delta y} = I(x, y+1) - I(x, y-1) \qquad F_x = \begin{bmatrix} 1\\ 0\\ -1 \end{bmatrix}$$

• Derivative as a convolution operation; e.g., Sobel masks:

$$S_x = \begin{bmatrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{bmatrix} \qquad \qquad S_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & 2 & -1 \end{bmatrix}$$

Note: masks are **mirrored** in convolution

Along x direction

Along *y* direction
Filtering

**Detectors** 

# Similarity measures

• Filtering can also be used to determine similarity across images (e.g., to detect correspondences)

$$SAD = \sum_{i=-n}^{n} \sum_{j=-m}^{m} |l_1(x+i, y+j) - l_2(x'+i, y''+j)| \qquad \sum \text{absolute differences}$$
$$SAD = \sum_{i=-n}^{n} \sum_{j=-m}^{m} [l_1(x+i, y+j) - l_2(x'+i, y''+j)]^2 \qquad \sum \text{squared differences}$$

### Detectors

- **Goal:** detect **local features**, i.e., image patterns that differ from immediate neighborhood in terms of intensity, color, or texture
- We will focus on
  - Edge detectors
  - Corner detectors

Vis. & Underst. of CNNs

Detectors

# Edge detectors

• Edge: region in an image where there is a significant change in intensity values along one direction, and negligible change along the orthogonal direction

In 1D

Magnitude of  $1^{st}$  order derivative is large,  $2^{nd}$  order derivative is equal to zero

Filtering

Detectors

# Criteria for "good" edge detection

- Accuracy: minimize false positives and negatives
- Localization: edges must be detected as close as possible to the true edges
- Single response: detect one edge per real edge in the image

Filtering

Detectors

# Strategy to design an edge detector

Two steps:

- **Smoothing:** smooth the image to reduce noise prior to differentiation (step 2)
- **Differentiation:** take derivatives along x and y directions to find locations with high gradients

### A better implementation

• Convolution theorem:

$$s'(x) = \frac{\delta}{\delta x} * (g_{\sigma}(x) * I(x)) = \underbrace{(\frac{\delta}{\delta x} * g_{\sigma}(x))}_{g'_{\sigma}(x)} * I(x)$$

### Edge detection in 2D

Ind the gradient of smoothed image in both directions

$$\nabla S := \begin{bmatrix} \frac{\delta}{\delta_X} * (G_{\sigma} * I) \\ \frac{\delta}{\delta_Y} * (G_{\sigma} * I) \end{bmatrix} = \begin{bmatrix} (\frac{\delta}{\delta_X} * G_{\sigma}) * I \\ (\frac{\delta}{\delta_Y} * (G_{\sigma}) * I) \end{bmatrix} = \begin{bmatrix} (G_{\sigma,x}) * I \\ (G_{\sigma,y}) * I \end{bmatrix} := \begin{bmatrix} S_x \\ S_y \end{bmatrix}$$

- **②** Compute the magnitude  $|\nabla S| = \sqrt{S_x^2 + S_y^2}$  and discard pixels below a certain threshold
- **(**) Non-maximum suppression: identify local maxima of  $|\nabla S|$

# Canny edge detector

### Corner detectors

Key criteria for "good" corner detectors

- **Repeatability:** same feature can be found in multiple images despite geometric and photometric transformations
- **Distinctiveness:** information carried by the patch surrounding the feature should be as distinctive as possible

Vis. & Underst. of CNNs

Filtering

# Repeatability

#### Without repeatability, matching is impossible

Vis. & Underst. of CNNs

Filtering

Detectors

### Distinctiveness

Without distinctiveness, it is not possible to establish reliable correspondences; distinctiveness is key for having a useful descriptor

Detectors

### Corner detectors

Key criteria for "good" corner detectors

- Corner: intersection of two or more edges
- Geometric intuition for corner detection: explore how intensity changes as we shift a window

Flat: no changes in any direction

Edge: no change along the edge direction

# Properties of Harris detectors

- Widely used
- Detection is invariant to
  - Rotation  $\rightarrow$  geometric invariance
  - Linear intensity changes  $\rightarrow$  photometric invariance
- Detection is not invariant to
  - Scale changes
  - Geometric affine changes
- Scale-invariant detection, such as
  - Harris-Laplacian
  - in SIFT (specifically, Difference of Gaussians (DoG))

### Descriptors

- **Goal:** describe keypoints so that we can compare them across images or use them for object detection or matching
- Desired properties:
  - Invariance with respect to pose, scale, illumination, etc.
  - Distinctiviness

Filtering

Detectors

# Simplest descriptor

- Naive descriptor: associate with a given keypoint an  $n \times m$  window of pixel intensities centered at that keypoint
- Window can be normalized to make it invariant to illumination

Filtering

Detectors
